

Title	21 W Standby Power Supply using TNY280P
Specification	Input: 85 – 295 VAC (110 – 420 VDC) Outputs: 5 V / 4 A; 15 V / 67 mA
Application	General PC-Standby Supply
Author	Power Integrations Applications Department
Document Number	DER-114
Date	June 28, 2006
Revision	1.0

Summary and Features

- High standby efficiency: P_{IN} < 0.70 W @ P_{OUT} = 0.5 W, at 230 VAC input
- Under-voltage lockout (UVLO) function: glitch-free startup and shutdown
- Two means of implementing output overvoltage protection (OVP)
- EEL22 transformer core meets clearance and creepage requirements
- Output overload, short circuit and open feedback loop protection

The products and applications illustrated herein (including circuits external to the products and transformer construction) may be covered by one or more U.S. and foreign patents or potentially by pending U.S. and foreign patent applications assigned to Power Integrations. A complete list of Power Integrations' patents may be found at *www.powerint.com*.

Important Note:

Although this board is designed to satisfy safety isolation requirements, the engineering prototype has not been agency approved. Therefore, all testing should be performed using an isolation transformer to provide the AC input to the prototype board.

1 Introduction

This engineering report describes a universal input 5 V, 4 A power supply designed around a TNY280P device from the *TinySwitch-III* family of ICs. Although designed as an auxiliary or bias supply for a personal computer (PC) power supply, this design can also be used as a general-purpose evaluation platform for *TinySwitch-III* devices.

Typically, PC power supplies have a power factor corrected (PFC) input stage. However, since the bias supply must operate before the PFC stage is active, this supply has been designed for universal input operation.

Input rectification and input storage capacitance have been included, for evaluation purposes. This stage and the EMI filter components would normally be part of the main PC supply, in an actual application.

This report contains the power supply specification, the circuit diagram, a complete bill of materials (BOM), the *PI XIs* transformer spreadsheet design results, complete transformer documentation, the printed circuit board (PCB) layout and relevant performance data.

3 Schematic

4 Circuit Description

This dual output converter is configured as a Flyback. The main output provides 4 A at 5 V, while the bias winding on transformer T1 is used to generate a 15 V output that can supply up to 67 mA. The converter will operate over an input voltage range of 85 - 295 VAC or 100 - 420 VDC. The 5 V output is referenced to a TL431 located on the secondary side, and feedback is passed back to the primary through optocoupler (U2).

4.1 Input Rectifier & filter

This circuit is designed for standby applications and components F1, RT1, D1-D4 & C1 are only provided for standalone testing. Fuse F1 will effectively isolate the converter from the supply source in the event of short circuit failure. Thermistor RT1 limits the inrush current at startup. Diodes D1, D2, D3 & D4 form a bridge rectifier, which charges the bulk storage capacitor C1.

4.2 TNY280 Primary

The TNY280P device (U1) is an integrated circuit, which includes a power MOSFET, an oscillator, control, start-up and protection functions.

A clamp circuit (D5, VR1, C3, R1 & R3) limits the voltage that appears on the drain of U1 each time its MOSFET turns off. During normal operation VR1 does not conduct and clamping is performed by D5, C3, R1 & R3. Typically, VR1 will only conduct during fault conditions such as overload. This approach allows the RCD clamp (R1, R3, C3 & D5) to be sized for normal operation, which maximizes efficiency at light load.

The output of the bias/auxiliary supply winding is rectified by diode D6 and filtered by capacitor C4. The rectified and filtered output of the bias winding (terminals J5 & J6) can be used to power external circuitry on the primary side, such as the PFC and main converter control circuits. The bias winding is also used to supply current to the TNY280 BYPASS/MULTIFUNCTION (BP/M) pin during steady state operation. The value of R4 is selected to deliver the IC supply current to the BP/M pin, thereby inhibiting the internal high-voltage current source that normally charges the BP/M pin capacitor (C2). This results in reduced input power consumption under light load and no load conditions.

Capacitor C2 provides high frequency decoupling of the internally generated 5.85 V IC supply voltage. Three different capacitor values could be used for C2, which would select one of three internal current limit sets. A 0.1 uF capacitor was used in this design, which selects the standard current limit set for a TNY280P.

The transistor of optocoupler U2 pulls current out of the ENABLE/UNDER-VOLTAGE (EN/UV) pin of U1. The IC keeps switching as long as the current drawn from its EN/UV pin is less than 90 μ A. It stops switching whenever the current drawn from the EN/UV pin exceeds that threshold, which ranges from 90 μ A to 150 μ A (with the typical value being 115 μ A). By enabling and disabling switching pulses, the feedback loop regulates the output voltage of the power supply.

An internal state machine sets the MOSFET current limit to one of four levels, depending on the main output load current. This ensures that the effective switching frequency remains above the audible frequency range. The lowest current limit (used at no-load) makes the transformer flux density so low that dip-varnished transformers produce no perceptible audible noise.

4.3 Output Rectification

Diode D7 rectifies the main output. Low ESR capacitors C7, C8 & C9 attenuate the switching ripple. A post filter (L1 & C10) further reduces switching ripple and noise on the main output.

4.4 Output Feedback

Resistors R6 and R7 form a voltage divider network. A portion of the output voltage is fed into the input terminal of the TL431 (U3). The TL431 varies its cathode voltage in an attempt to keep its input voltage constant (equal to $2.5 \text{ V}, \pm 2\%$). As the cathode voltage changes, the current through the LED and transistor within U2 change. Whenever the EN/UV pin current exceeds its threshold, the next switching cycle is disabled. Whenever the EN/UV pin current falls below the threshold, the next switching cycle is enabled. As the load is reduced, the number of enabled switching losses. This results in almost constant efficiency down to very light loads, which is ideal for meeting energy efficiency requirements. Capacitor C12 rolls off the gain of U3 with frequency, to ensure stable operation. Capacitor C11 prevents the output voltage from overshooting at startup.

4.5 UV Lockout

Optional resistors R11 and R12–connected between the DC bus and the EN/UV pin of U1–enable the under-voltage lockout function. When these resistors are used, start-up is inhibited until the current into the EN/UV pin exceeds 25 μ A. The values of R11 and R12 sets a startup voltage threshold that prevents output voltage glitches when the input voltage is abnormally low, such as when the AC input capacitor is discharging during shutdown. Additionally, the UVLO status is checked whenever a loss of regulation occurs–such as during an output overload or short-circuit. This effectively latches U1 off until the input voltage is removed and reapplied. With the values of R11 and R12 shown in figure 2, the UVLO threshold is approximately 100 VDC (71 VAC).

4.6 OVP

This supply has two different overvoltage protection circuits. The first OVP function is provided by VR2 and the latching shutdown function built into U1. If the feedback loop became an open circuit–due to the failure of U2, for example–the main output voltage and the bias winding voltage would both rise. Once the bias voltage exceeded the sum of the voltage across VR2 and the BP/M pin voltage, current would flow into the BP/M pin. When that current exceeds the OV shutdown threshold (~5.5 mA), the latching shutdown function is triggered and MOSFET switching is disabled. MOSFET switching remains disabled until the BP/M pin capacitor (C2) is discharged below 4.8 V.

The second OVP function is provided by VR3, U4 and R10, and is enabled when jumpers JP1 and JP2 are installed (forms a second feedback loop). If the primary feedback loop became an open circuit, the output voltage would rise. The EN/UV pin would be pulled low once the output voltage exceeded the voltage across VR3 and the LED within U4. The output voltage would then be regulated at a slightly higher voltage than that of the primary feedback loop.

Diodes	MBR1060		Recommended Diodes for this output
CMS1	1550	Cmils	Output Winding Bare Conductor minimum circular mils
AWGS1	18	AWG	Wire Gauge (Rounded up to next larger standard AWG value)
DIAS1	1.03	mm	Minimum Bare Conductor Diameter
ODS1	2.32	mm	Maximum Outside Diameter for Triple Insulated Wire

9 Performance Data

All measurements performed at room temperature, 60 Hz input frequency.

9.1 Efficiency

(4 A Load on 5 V Output)

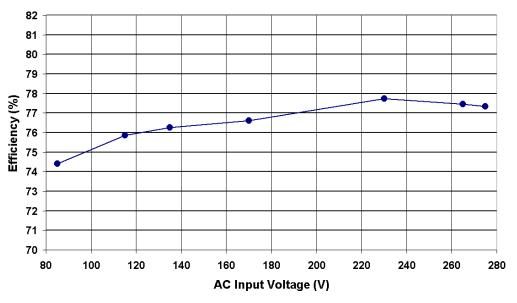

Figure 6 – Efficiency vs. Input Voltage, Room Temperature, 60 Hz.

9.2 No-load Input Power

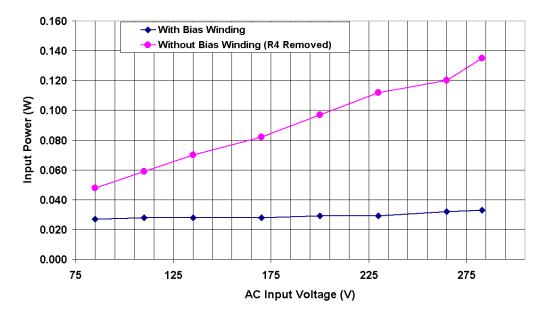

Figure 7 – Zero Load Input Power vs. Input Line Voltage, Room Temperature, 60 Hz.

9.3 0.5 W (5 V, 0.1 A) Load Input Power

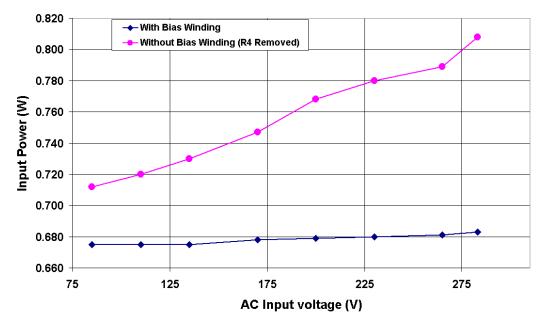

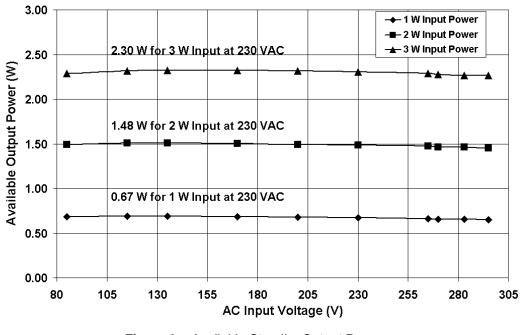

Figure 8 – 0.5 W Load – Input Power with & without bias winding.

9.4 Available Standby Output Power

The chart below shows the available output power vs. line voltage for an input power consumption of 1, 2 & 3 watts respectively. ON/OFF control is valuable in maintaining high efficiency under light load conditions, and helps meet many standby requirements.

9.5 Regulation

9.5.1 Load

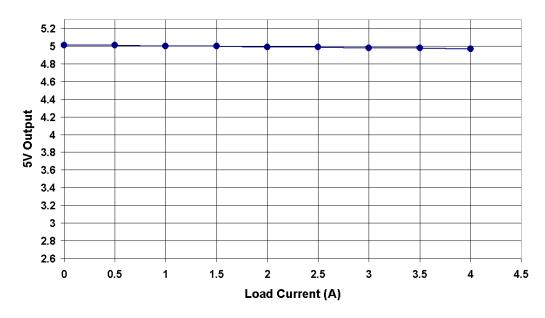

Figure 10 – Load Regulation, Room Temperature.

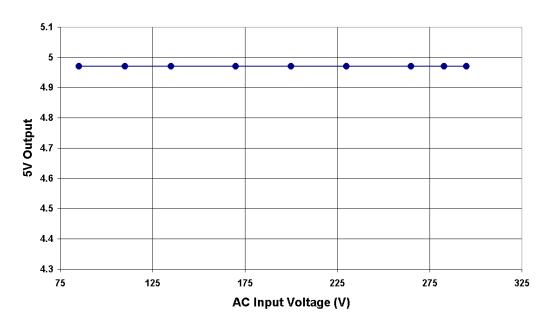

Figure 11 – Line Regulation, Room Temperature, Full Load.

10 Thermal Performance

Temperature measurement of key components were taken using T-type Thermocouples. The thermocouples were attached directly to the SOURCE pin of the TNY280P device and the case of the output rectifier. The thermocouples were glued to the output capacitor & to the external core and winding surfaces of the transformer T1.

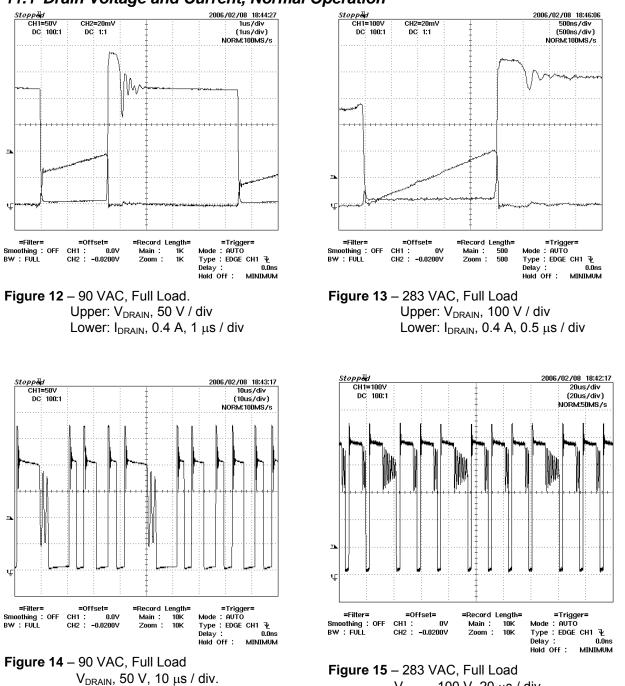

The cooling of the TNY280P is achieved through the copper plane on the PCB. It is necessary to provide adequately large copper area on the PCB attached to the SOURCE pins (5, 6, 7 and 8) of the DIP-8 package, to achieve the required cooling (se figure 3).

These results indicate an acceptable temperature rise of key components when ambient is increased to 50 °C.

ltem	Temperature (°C)				
nem	85 VAC	115 VAC	230 VAC		
Ambient	25	25	25		
Transformer (T1) core	49.9	45	44		
Transformer (T1) coil	52.4	50.6	49.6		
Tiny-Switch (U1)	62.3	56.3	49		
Rectifier (D7) case	75	75	74

V_{OUT}, 1 V, 5 ms / div.

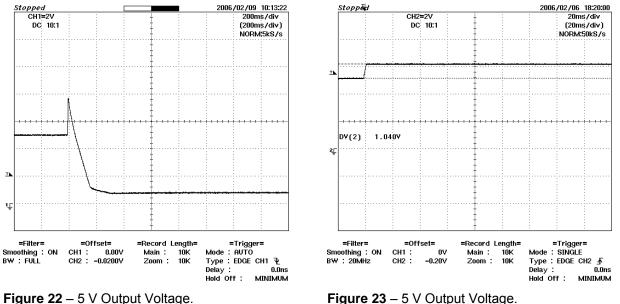

V_{OUT}, 1 V, 5 ms / div

V_{OUT}, 1 V, 5 ms / div.

11.4 OV Shutdown

Two different OV Protection circuits can be designed with Tiny Switch-III. Figure 22 shows operation of primary side OV protection circuit (JP1 and JP2 not installed) and feedback disconnected to cause OV condition at the output.

Figure 23 shows OV protection offered by VR3, U4 & R10 circuit (Feedback disconnected during operation to cause OV condition at output).

V_{OUT}, 2 V, 200 ms / div

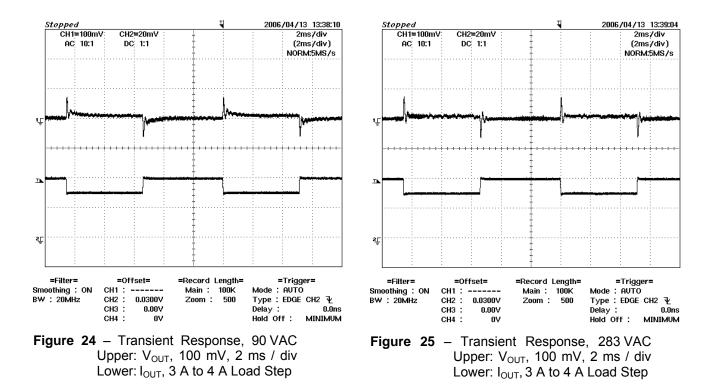

V_{OUT}, 2 V, 20 ms / div.

11.5 Load Transient Response (3 A to 4 A Load Step)

In the figures shown below, signal averaging was used to enable better viewing of the load transient response. The oscilloscope was triggered using the load current step as a trigger source. Since the output switching and line frequency occur essentially at random with respect to the load transient, contributions to the output ripple from these sources will average out, leaving only the contribution from the load step response.

The waveforms (Figures 24 and 25) show an instantaneous voltage change of 70 mV for a 75% - 100% step load change. Increasing the size of the output filter capacitor minimizes the 70 mV change.

11.6 Output Ripple Measurements

11.6.1 Ripple Measurement Technique

For DC output ripple measurements, a modified oscilloscope test probe must be utilized in order to reduce spurious signals due to pickup. Details of the probe modification are provided in Figure 26 and Figure 27.

The 5125BA probe adapter is affixed with two capacitors tied in parallel across the probe tip. The capacitors include one (1) 0.1 μ F/50 V ceramic type and one (1) 1.0 μ F/50 V aluminum electrolytic. *The aluminum electrolytic type capacitor is polarized, so proper polarity across DC outputs must be maintained (see below).*

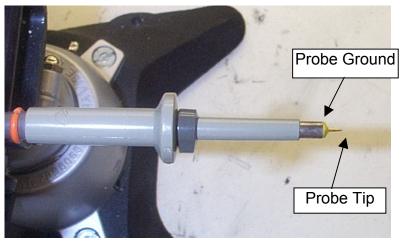

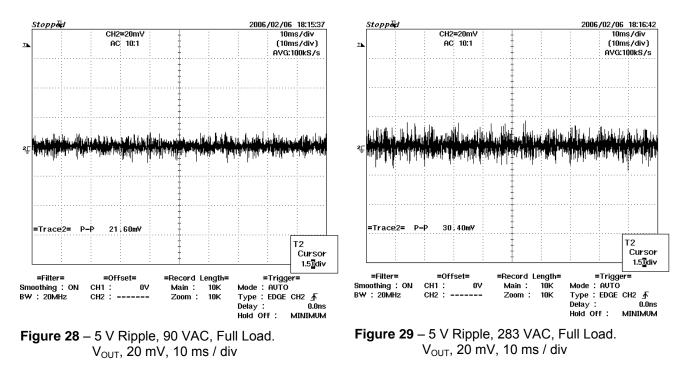

Figure 26 – Oscilloscope Probe Prepared for Ripple Measurement. (End Cap and Ground Lead Removed)

Figure 27 – Oscilloscope Probe with Probe Master 5125BA BNC Adapter. (Modified with wires for probe ground for ripple measurement, and two parallel decoupling capacitors added)

11.6.2 Measurement Results

12 Design Notes:

- 1. Use of sufficient copper area directly under the TNY280P device, connected to the SOURCE pins of the IC is recommended for effective cooling. Generally, 1 square inch of symmetrical copper (2 oz) should be sufficient. However, actual temperature measurements should be used to determine adequacy. This is especially important when using the *TinySwitch-III* devices at or near the power levels specified on the datasheet output power table.
- 2. A dummy load (R2 in figure 2) was used in this design to ensure appropriate line & load regulation of the auxiliary output. Since this output is not directly regulated, it has a slightly higher output voltage when unloaded. The value of R13 should be selected, based on the current drawn by the external circuit that loads the auxiliary output. The filtering of the auxiliary output, and the need for an additional filter stage should be carefully evaluated, based on the load circuit's requirements.
- 3. R13 & C4 form a RC filter to reduce the ripple voltage on the auxiliary output
- 4. In many applications, the snubber circuit (R3, C3 & R1) can be eliminated, depending on the EMC compliance requirements of the system.
- 5. The size and specification of the output diode (D7) heat sink depends on load and operating conditions. In some designs, where augmented airflow is available, a small surface-area heat sink may be sufficient.
